Historically, there has been a need for the thermal transfer of information from an information carrying medium to another medium or substrate. For example, thermal transfer printing has been used to print information such as messages, advertising, or other similar information on a heat transfer film, which can then be applied to a substrate such as a garment, tee shirt, pajama top, etc. Alternatively, the heat transfer printing may be applied to a substrate that already has text or other information, for example, self-adhesive stickers. Printing information on a substrate by employing a thermal transfer process requires the medium or substrate that contains the information to be thermally transferred to be in proximity with a ribbon or sheet containing an ink that is transferred to the substrate. Typically, such a thermal transfer printing process employs a print head that is inked up to a first plate that contacts the substrate to be printed. The inked plate is pressed against the substrate and a current is applied to the print head. As a result, the print head heats up and transfers the inks to the substrate, as the substrate passes under the print head. Once the inks have been sufficiently transferred, the ink from the plate is passed on to a ribbon or sheet that has been stored in a thermal transfer apparatus. The ribbon or sheet then travels through a nip between a presser and a transfer roller. The presser presses the inked ribbon or c6a93da74d
